Application No. 10/538,118 March 20, 2008 Reply to the Office Action dated November 21, 2007 Page 2 of 10

AMENDMENTS TO THE SPECIFICATION:

Please REPLACE the paragraph on page 3, lines 6-15 of the Substitute Specification with the following amended paragraph:

Another person proposed a method of making a plastic substrate of a composite material, in which a resin and a filler are mixed together, in order to increase the thermal resistance and dimensional stability thereof. A substrate made of a composite material will be referred to herein as a "composite substrate". For example, Japanese Patent Application Laid-Open Publication No. 41-248111-2812 discloses a reflective conductive substrate including a composite substrate, which is obtained by impregnating a piece of glass fiber cloth with a resin.

Please REPLACE the paragraph bridging pages 17 and 18 of the Substitute Specification with the following amended paragraph:

As shown in FIG. 1(c), in the composite substrate 10, the principal refractive index n_x of the x-axis, along which the fibers 11 are arranged, is greater than the principal refractive index n_y of the y-axis or the principal refractive index n_z of the z-axis. The principal refractive indices n_y and n_z of the y- and z-axes are substantially equal to each other. The principal refractive indices of the composite substrate 10 satisfy the relationship $\underline{n_x} = n_y = n_x = n_z$. Accordingly, light that has been vertically incident onto the principal surface of the composite substrate 10 has an in-plane retardation Rp between a polarized component (linearly polarized light ray) parallel to the x-axis and a polarized component (linearly polarized light ray) parallel to the y-axis. The magnitude of the in-plane retardation Rp is given by Rp=d · ($n_y = n_x$), where d is the thickness of the composite substrate 10 normally include not only the in-plane retardation Rp but also a retardation Rth in thickness direction as well.

Application No. 10/538,118 March 20, 2008 Reply to the Office Action dated November 21, 2007 Page 3 of 10

Please REPLACE the paragraph bridging pages 23 and 24 of the Substitute Specification with the following amended paragraph:

The composite substrate 20 includes fibers 21 and a resin matrix 22. The fibers 21 are arranged in two orthogonal directions (e.g., in x-axis and y-axis directions in this preferred embodiment) within a substrate plane. In this preferred embodiment, the fibers 21 are arranged in two different layers such that the fibers 21 arranged in the x-axis direction do not contact with the fibers 21 arranged in the y-axis direction as shown in FIG. 42(b). Alternatively, the fibers 21 arranged in the x-axis direction may contact with the fibers 21 arranged in the y-axis direction. That is to say, the fibers 21 may be prepared as a fabric (e.g., a woven fabric). When the fibers 21 are prepared as a fabric, the fibers 21 may be woven by any of various weaving methods including plain weaving, sateen weaving and twill weaving.

Please REPLACE the paragraph on page 35, lines 7-17 of the Substitute Specification with the following amended paragraph:

Each of the plastic substrates used as the substrates 81 and 82 includes fibers that are arranged in two orthogonal directions 86 as in the plastic substrate 20 or 30 shown in FIG. 2 or 3. For example, the substrate 81 may be a counter substrate in which a counter electrode is provided on one principal surface of the substrate 81 so as to face the liquid crystal layer 83. On the other hand, the substrate 82 may be an active-matrix substrate in which transparent pixel electrodes, TFTs and other circuit components (none of which are shown) are provided on one principal surface of the substrate 82 so as to face the liquid crystal layer 6383, too.
